About This Book

*vCenter Single Sign-On Programming Guide* describes how to use the VMware® vCenter Single Sign On API. VMware provides different APIs and SDKs for different applications and goals. The vCenter Single Sign On SDK supports the development of vCenter clients that use SAML token authentication for access to vSphere environments.

To view the current version of this book as well as all VMware API and SDK documentation, go to [http://www.vmware.com/support/pubs/sdk_pubs.html](http://www.vmware.com/support/pubs/sdk_pubs.html).

Revision History

This book is revised with each release of the product or when necessary. A revised version can contain minor or major changes. Table 1 summarizes the significant changes in each version of this book.

<table>
<thead>

<tr>
<td>10Sep2012</td>
<td>vCenter Single Sign On SDK V1.0 documentation.</td>
</tr>
</tbody>
</table>

Intended Audience

This book is intended for anyone who needs to develop applications using the vCenter Single Sign On SDK. Developers typically create vCenter Single Sign On client applications using Java to access the vCenter Single Sign On Server. An understanding of Web Services technology and some programming background in one of the stub languages (Java) is required.

VMware Technical Publications Glossary

VMware Technical Publications provides a glossary of terms that might be unfamiliar to you. For definitions of terms as they are used in VMware technical documentation go to [http://www.vmware.com/support/pubs](http://www.vmware.com/support/pubs).

Document Feedback

VMware welcomes your suggestions for improving our documentation. Send your feedback to docfeedback@vmware.com.
A vCenter Single Sign-On client connects to the vCenter Single Sign On Server to obtain a security token that contains authentication claims required for operations in the vSphere environment. The vCenter Single Sign On client API supports operations to acquire, renew, and validate tokens.

This chapter includes the following topics:
- vCenter Single Sign On Overview
- vCenter Single Sign On Client API
- Acquiring a SAML Token
- vCenter Single Sign On SOAP Message Structure
- vCenter Single Sign On SDK

vCenter Single Sign On Overview

To support the requirements for secure software environments, software components require authorization to perform operations on behalf of a user. In a single sign-on environment, a user provides credentials once, and components in the environment perform operations based on the original authentication. vCenter Single Sign On authentication can use the following identity store technologies:
- Windows Active Directory
- OpenLDAP (Lightweight Directory Access Protocol)
- Local user accounts (vCenter Single Sign On Server resident on the vCenter Server machine)
- vCenter Single Sign On user accounts

For information about configuring identity store support, see vSphere Installation and Setup and vSphere Security in the VMware Documentation Center.

In the context of single sign-on, the vSphere environment is a collection of services and solutions, each of which potentially requires authentication of clients that use the service or solution. Examples of solutions that might support single sign-on include vShield, SRM (Site Recovery Manager), and vCO (vCenter Orchestrator). Because a service can use another service, single sign-on provides a convenient mechanism to broker authentication during a sequence of vSphere operations.

The vCenter Single Sign On Server provides a Security Token Service (STS). A vCenter Single Sign On client connects to the vCenter Single Sign On server to obtain a token that represents the client. A token uses the Security Assertion Markup Language (SAML) which is an XML encoding of authentication data. It contains a collection of statements or claims that support client authentication. Examples of token claims include name, key, and group.
There are two types of vCenter Single Sign On tokens.

- Holder-of-key tokens provide authentication based on security artifacts embedded in the token. Holder-of-key tokens can be used for delegation. A client can obtain a holder-of-key token and delegate that token for use by another entity. The token contains the claims to identify the originator and the delegate. In the vSphere environment, a vCenter Server obtains delegated tokens on a user’s behalf and uses those tokens to perform operations.

- Bearer tokens provide authentication based only on possession of the token. Bearer tokens are intended for short-term, single-operation use. A bearer token does not verify the identity of the user (or entity) sending the request. It is possible to use bearer tokens in the vSphere environment, however there are potential limitations:
  - The vCenter Single Sign On Server may impose limitations on the token lifetime, which would require you to acquire new tokens frequently.
  - Future versions of vSphere might require the use of holder-of-key tokens.

The following figure shows a vCenter client that uses a SAML token to establish a session with a vCenter Server.

**Figure 1-1. Single Sign-On in the vSphere Environment – vCenter Server LoginByToken**

The vCenter client also operates as a vCenter Single Sign On client. The vCenter Single Sign On client component handles communication with the vCenter Single Sign On Server.

1. The vCenter Single Sign On client sends a token request to the vCenter Single Sign On Server. The request contains information that identifies the principal. The principal has an identity in the identity store. The principal may be a user or it may be a software component. In this scenario, the principal is the user that controls the vCenter client.

2. The vCenter Single Sign On Server uses the identity store to authenticate the principal.

3. The vCenter Single Sign On Server sends a response to the token request. If authentication is successful, the response includes a SAML token.

4. The vCenter client connects to the vCenter Server and calls the `SessionManager.LoginByToken` method. The login request contains the SAML token.

The figure shows the vCenter Server, vCenter Single Sign On Server, and identity store as components running on separate machines. You can use different vCenter Single Sign On configurations.
- A vCenter Single Sign On Server can operate as an independent component running on its own machine. The vCenter Single Sign On Server can use a remote identity store or it can manage user accounts in its own internal identity store.

- A vCenter Single Sign On Server can operate as an embedded component running on the vCenter Server machine. In this configuration, the vCenter Single Sign On Server can use a remote identity store, its own internal identity store, or it can access user accounts on the vCenter Server machine.

For information about installing and configuring the vCenter Single Sign On Server, see *vSphere Installation and Setup* and *vSphere Security* in the VMware Documentation Center.

**vCenter Single Sign On Client API**

The vCenter Single Sign On client API is described in the WSDL (Web Service Definition Language) file that is included in the vCenter Single Sign On SDK. This API defines a set of request operations that correspond to the WS-Trust 1.4 bindings. The set of operations includes Issue, Renew, Validate, and Challenge requests.

- **Issue** – Obtains a token from a vCenter Single Sign On Server.
- **Renew** – Renews an existing token.
- **Validate** – Validates an existing token.
- **Challenge** – Part of a negotiation with a vCenter Single Sign On Server to obtain a token.

The vCenter Single Sign On SDK includes Java bindings for the vCenter Single Sign On WSDL. The SDK also contains sample code that includes a JAX-WS implementation of SOAP header methods that support the vCenter Single Sign On security policies. The security policies are based on the WS-SecurityPolicy standard. Security policies specify the elements that provide SOAP message security. The SOAP header methods insert digital signatures, certificates, and SAML tokens into the SOAP message for vCenter Single Sign On requests. See “vCenter Single Sign On Security Policies” on page 8 and “vCenter Single Sign On SDK” on page 11.

**Acquiring a SAML Token**

To obtain a security token from a vCenter Single Sign On Server, the vCenter Single Sign On client calls the Issue method, which sends a SOAP message that contains a token request and authentication data. This section describes a token request that uses a certificate to obtain a holder-of-key token. When the client creates the token request, it also inserts timestamp, signature, and certificate data into the SOAP security header. The vCenter Single Sign On SDK provides Java packages that support SOAP header manipulation.

The following figure represents the content of an Issue request and the response containing a SAML token.

*Figure 1-2. Issue - vCenter Single Sign On Token Request and Response*
When the vCenter Single Sign On Server receives the issue request, it performs the following operations to generate a token:

- Uses the timestamp to validate the request.
- Validates the certificate.
- Uses the certificate to validate the digital signature.
- Uses the certificate subject to authenticate the request. Authentication is obtained from the identity store that is registered with the vCenter Single Sign On Server.
- Generates a token that specifies the principal – the vCenter Single Sign On client – as the token subject.

**vCenter Single Sign On Security Policies**

Web service security policies define the requirements for secure communication between a Web service and a client. vCenter Single Sign On security policies are based on the WS-Policy framework and WS-SecurityPolicy specifications. A policy identifies specific elements for token requests. Based on the policy requirements, a vCenter Single Sign On client will insert data into the SOAP security header for the token request.

vCenter Single Sign On defines security policies for end user access, solution access, and for token exchange. The policies stipulate the following elements:

- Security certificates (x509V3, x509PKIPathV1, x509PKCS7, or WssSamlV20Token11)
- Message timestamps
- Security binding (transport)
- Encryption algorithm (Basic256Sha256)

vCenter Single Sign On security policies specify that the body of the SOAP message for a holder-of-key token must be signed. Bearer tokens require only the username and timestamp tokens.

**NOTE** The vCenter Single Sign On Server issues SAML tokens to represent client authentication. The standards documentation also uses the term “token” to refer to claims and certificate data that is inserted into SOAP security headers.
The following table shows the vCenter Single Sign On policies and identifies the requirements for each policy.
The vCenter Single Sign On WSDL defines these policies for use with the vCenter Single Sign On methods.

**Table 1-1. vCenter Single Sign On Policies**

</tbody>
</table>

**vCenter Single Sign On SDK Support for vCenter Single Sign On Security Policies**

The vCenter Single Sign On SDK provides Java utilities that support the vCenter Single Sign On security policies. Your vCenter Single Sign On client can use these utilities to create digital signatures and supporting tokens, and insert them into SOAP headers as required by the policies. The SOAP header utilities are defined in files that are located in the samples directory:

```bash
SDK\sso\java\JAXWS\samples\com\vmware\sso\client\soaphandlers
```

See “Using Handler Methods for SOAP Headers” on page 22.

**Connecting to a vCenter Single Sign On Server**

When a vCenter Single Sign On client connects to a vCenter Single Sign On server, it must specify the server URL as the endpoint for the token request message. The endpoint specification uses the following format:

```
https://hostname|IPaddress:7444/ims/STSService
```

The port number and path suffix (7444/ims/STSService) is required. 7444 is the default port number. See “Sending a Request for a Security Token” on page 24 for an example of setting the endpoint for a token request. You can change the port number during vCenter Single Sign On Server installation.
Token Delegation

Holder-of-key tokens can be delegated to services in the vSphere environment. A service that uses a delegated token performs the service on behalf of the principle that provided the token. A token request specifies a DelegateTo identity. The DelegateTo value can either be a solution token or a reference to a solution token.

Components in the vSphere environment can use delegated tokens. vSphere clients that use the LoginByToken method to connect to a vCenter Server do not use delegated tokens. The vCenter Server will use a vSphere client’s token to obtain a delegated token. The vCenter Server will use the delegated token to perform operations on behalf of the user after the user’s vCenter session has ended. For example, a user may schedule operations to occur over an extended period of time. The vCenter Server will use a delegated token to support these operations.

Token Lifetime - Clock Tolerance

A SAML token contains information about the lifetime of a token. A SAML token uses the NotBefore and NotOnOrAfter attributes of the SAML Conditions element to define the token lifetime.

During a token’s lifetime, the vCenter Single Sign On server considers any request containing that token to be valid and the server will perform renewal and validation operations on the token. The lifetime of a token is affected by a clock tolerance value that the vCenter Single Sign On server applies to token requests. The clock tolerance value accounts for differences between time values generated by different systems in the vSphere environment. The clock tolerance is 10 minutes.

Challenge (SSPI)

The vCenter Single Sign On Server supports the use of SSPI (Security Support Provider Interface) for client authentication. SSPI authentication requires that both the client and server use security providers to perform authentication. At the beginning of a vCenter Single Sign On Server session, the vCenter Single Sign On client and vCenter Single Sign On Server exchange data. Each participant will use its security provider to authenticate the data it receives. The authentication exchange continues until both security providers authenticate the data.

The vCenter Single Sign On client API provides a challenge request for client participation in SSPI authentication. The following sequence describes the challenge protocol.

- vCenter Single Sign On client sends an issue request to the vCenter Single Sign On Server. The request contains the client credentials.
- vCenter Single Sign On Server uses its security provider to authenticate the client. The Server returns a RequestSecurityTokenResponseType object in response to the issue request. The response contains a challenge.
- vCenter Single Sign On client uses its security provider to authenticate the vCenter Single Sign On Server response. To continue the authentication exchange, the client sends a challenge request to the vCenter Single Sign On Server. The request contains the resolution to the Server's challenge and it can also contain a challenge from the vCenter Single Sign On client.
- vCenter Single Sign On Server uses its security provider to authenticate the client's response. If there are still problems, the Server can continue the authentication exchange by returning a response with an embedded challenge. If authentication is successful, the vCenter Single Sign On Server returns a SAML token to complete the original issue request.

To exchange challenge data, the vCenter Single Sign On client and vCenter Single Sign On Server use the following elements defined for both RequestSecurityTokenType and RequestSecurityTokenResponseType objects.

- Context attribute
- BinaryExchange element
vCenter Single Sign On SOAP Message Structure

The requirements listed in the following table apply to the SOAP message structure in vCenter Single Sign On message exchange.

<table>
<thead>
<tr>
<th>Element</th>
<th>Message Requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>SOAP envelope</td>
<td>All <code>&lt;wst:RequestSecurityToken&gt;</code>, <code>&lt;wst:RequestSecurityTokenResponse&gt;</code>, and <code>&lt;wst:RequestSecurityTokenResponseCollection&gt;</code> elements must be sent as the single direct child of the body of a SOAP 1.1 <code>&lt;S11:Envelope&gt;</code> element. Use HTTP POST to send all vCenter Single Sign On SOAP messages over an SSL/TLS protected channel. Set the SOAPAction HTTP header field to the appropriate message binding. The <code>&lt;wsse:Security&gt;</code> header in an vCenter Single Sign On request must contain a <code>&lt;wsu:Timestamp&gt;</code> element.</td>
</tr>
</tbody>
</table>
| SOAP message signature | If a signature is applied to a request then it must include:  
  - Either the `<S11:Body>`, or the WS-Trust element as a direct child of the `<S11:Body>`  
  - The `<wsu:Timestamp>`, if present, in the `<S11:Header>`.  
  Exclusive canonicalization without comments (xml-exc-c14n) must be used prior to signature generation.  
  The signature certificate must either be carried either within a `<wsse:BinarySecurityToken>` or a `<saml:Assertion>` within `<wsse:Security>` header of the `<S11:Header>`.  
  The signature must contain a `<wsse:SecurityTokenReference>` that uses an internal direct reference to the `<wsse:BinarySecurityToken>`. |

vCenter Single Sign On SDK

The vCenter Single Sign On SDK is distributed as part of the VMware vSphere Management SDK. When you extract the contents of the distribution kit, the vCenter Single Sign On SDK is located in the `sso` sub-directory:

```
VMware-vSphere-SDK-build-num
   eam
   sms-sdk
   ssoclient
docs
   java
      JAXWS
         lib
         samples

vCenter Single Sign On SDK Examples

This manual describes two of the examples provided by the VMware SSO Client SDK:

- “vCenter Single Sign On Client Example (JAX-WS)” on page 21. This example shows how to obtain a holder-of-key token from the vCenter Single Sign On Server.
- “LoginByToken Example (JAX-WS)” on page 27. This example shows how to use the token to login to vCenter Server.

The SDK contains additional examples that show how to use the vCenter Single Sign On client API to acquire, renew, and validate tokens. The following table lists the sample files in the SDK:

This chapter contains descriptions of the methods and data structures defined for the vCenter Single Sign On client API.

- “vCenter Single Sign On Client API Methods” on page 13
- “vCenter Single Sign On API Data Structures” on page 15

vCenter Single Sign On Client API Methods

The vCenter Single Sign On client API consists of the following methods:

- Issue
- Renew
- Validate
- Challenge

**Issue**

Sends a security token request to a vCenter Single Sign On Server.

**Method Signature**

```plaintext
Issue (requestSecurityToken : RequestSecurityTokenType)
  returns RequestSecurityTokenResponseCollectionType
```

**Parameter**

- `requestSecurityToken : RequestSecurityTokenType` – The following RequestSecurityTokenType elements are required for an Issue request; the remaining elements are optional.
  - `RequestType` – Must be the URL “http://docs.oasis-open.org/ws-sx/ws-trust/200512/Issue”.
  - `Sig` attribute (UseKey element) – Specifies a security token that contains an existing certificate key for subject confirmation.
  - `Context` attribute – Required if you include a BinaryExchangeType element for SSPI authentication.

**Return Value**

- `RequestSecurityTokenResponseCollectionType` – Set of RequestSecurityTokenResponseType. A response contains a SAML token or a challenge requiring additional authentication data.
Comments
Sends a token request to a vCenter Single Sign On Server. The request message must contain security artifacts as determined by the vCenter Single Sign On policy used for the request. The vCenter Single Sign On Server will authenticate the user credentials in the request. For information about configuring user directory support for authentication, see vSphere Installation and Setup and vSphere Security in the VMware Documentation Center. If the vCenter Single Sign On Server requires information during SSPI authentication, it will negotiate with the vCenter Single Sign On client by embedding a challenge in the response.

Renew
Renews an existing SAML token.

Method Signature
Renew (token : RequestSecurityTokenType) returns RequestSecurityTokenResponseType

Parameter
token : RequestSecurityTokenType – Security token request containing a SAML token previously obtained from a vCenter Single Sign On Server. The token must be valid (not expired). The following RequestSecurityTokenType elements are required for a Renew request; the remaining elements are optional.

- RequestType – Must be the URL “http://docs.oasis-open.org/ws-sx/ws-trust/200512/Renew”.
- RenewTarget – Identifies the SAML token to be renewed.
- Sig attribute (UseKey element) – Specifies a security token that contains an existing certificate key for subject confirmation.
- Context attribute – Required if you include a BinaryExchangeType element for SSPI authentication.

Return Value
RequestSecurityTokenResponseType – Response containing the renewed token.

Comments
You can renew holder-of-key tokens only. In addition to the the required token request elements shown above, the Renew request SOAP header must contain security elements according to the security policy.

Validate
Validates an existing SAML token.

Method Signature
Validate (token : RequestSecurityToken) returns RequestSecurityTokenResponseType

Parameter
token : RequestSecurityTokenType – Security token request containing a SAML token previously obtained from a vCenter Single Sign On Server. The following RequestSecurityTokenType elements are required for a Validate request; the remaining elements are optional.

- RequestType – Must specify the URL “http://docs.oasis-open.org/ws-sx/ws-trust/200512/Validate”.
- ValidateTarget – Identifies the SAML token to be validated.
- Sig attribute (UseKey element) – Specifies a security token that contains an existing certificate key.
- Context attribute – Required if you include a BinaryExchangeType element for SSPI authentication.
Return Value

RequestSecurityTokenType – Response containing the validated token.

Comments

 Performs validation of the token and its subject. It includes but is not limited to validations of the following elements:

- Token signature
- Token lifetime
- Token subject
- Token delegates
- Group(s) to which the subject belongs

Challenge

Extends a token request to verify elements in the request.

Method Signature

Challenge (response : RequestSecurityTokenType) returns RequestSecurityTokenType

Parameter

response : RequestSecurityTokenType – Contains SSPI data in the BinaryExchange element.

Return Value

RequestSecurityTokenType – Response containing the validated token.

Comments

Part of a negotiation with a vCenter Single Sign On Server to resolve issues related to SSPI authentication.

vCenter Single Sign On API Data Structures

Use the following objects for the vCenter Single Sign On methods.

- RequestSecurityTokenType
- RequestSecurityTokenResponseCollectionType
- RequestSecurityTokenResponseType
- LifetimeType
- RenewingType
- KeyTypeOpenEnum
- UseKeyType
- ParticipantsType
- ParticipantType
- EndpointReference
- BinaryExchangeType
- AdviceType
- AttributeType

RequestSecurityTokenType

Defines a set of token characteristics requested by the vCenter Single Sign On client. The vCenter Single Sign On client specifies this data object in a call to the Issue, Renew, and Validate methods. The vCenter Single Sign On Server may satisfy a request for a particular characteristic or it may use a different value in the issued token. The response to the token request contains the actual token values. See “RequestSecurityTokenResponseType” on page 17.
The vCenter Single Sign On API supports a subset of the `RequestSecurityTokenType` elements defined in the WS-Trust specification. The following table shows the supported elements and attributes. An item in the table is defined as an element in the WSDL unless explicitly identified as an attribute.

**Table 2-1. `RequestSecurityTokenType` Elements (vCenter Single Sign On)**

RequestSecurityTokenResponseType

Describes a single token.

| Table 2-3. RequestSecurityTokenResponseType Properties (vCenter Single Sign On) |
|-----------------|----------------|---------------------------------|
| **Element**     | **Datatype**  | **Description**                 |
| Context         | string        | RequestSecurityTokenResponse attribute specifying a URI (Uniform Resource Identifier) that identifies the original request. This attribute is included in the response if it was specified in the request. |
| TokenType       | string        | Identifies the type of token in the response. TokenType is specified as a URI (Uniform Resource Identifier), one of the following:  
| Lifetime        | LifetimeType  | Time period during which a token is valid. The lifetime in the token response is the actual lifetime assigned by the vCenter Single Sign On Server. The lifetime specifies creation and expiration values. |
| RequestedSecurityToken | RequestedSecurityTokenType | SAML token. |
| Renewing        | RenewingType  | Indicates whether or not the token can be renewed. By default, the vCenter Single Sign On Server will issue a renewable token. |
| BinaryExchange  | BinaryExchangeType | Contains data for challenge negotiation between vCenter Single Sign On client and vCenter Single Sign On Server. |
| KeyType         | string        | Indicates whether or not key cryptography is used. The KeyType is a string value corresponding to an enumerated type value. See KeyTypeOpenEnum. The value is a URI (Uniform Resource Identifier) that specifies the key type. |
### LifetimeType

Specifies the token lifetime. Used in RequestSecurityTokenType and RequestSecurityTokenResponseType.

#### Table 2-4. LifetimeType Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Datatype</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>created</td>

</tr>
</tbody>
</table>
| AttributeValue    | string   | List of values associated with the attribute. The AttributeValue structure depends on the following criteria:  
  ■ If the attribute has one or more values, the AttributeType contains one AttributeValue for each value. Empty attribute values are represented by empty AttributeValue elements.  
  ■ If the attribute does not have a value, the AttributeType does not contain an AttributeValue. |
This chapter describes a Java example of acquiring a vCenter Single Sign On security token.

- “vCenter Single Sign On Token Request Overview” on page 21
- “Using Handler Methods for SOAP Headers” on page 22
- “Sending a Request for a Security Token” on page 24

vCenter Single Sign On Token Request Overview

The code examples in the following sections show how to use the Issue method to acquire a holder-of-key security token. To see an example of using the token to login to a vCenter Server, see “LoginByToken Example (JAX-WS)” on page 27. The code examples in this chapter are based on the following sample file located in the vCenter Single Sign On SDK JAX-WS client samples directory:

`.../JAXWS/samples/com/vmware/sso/client/samples/AcquireHoKTokenByUserCredentialSample.java`

The `AcquireHoKTokenByUserCredentialSample` program creates a token request and calls the issue method to send the request to a vCenter Single Sign On Server. The program uses a sample implementation of Web services message handlers to modify the SOAP security header for the request message.

This example uses the username-password security policy (STSSecPolicy_UserPwd). This policy requires that the SOAP security header include a timestamp, username and password, and a digital signature and certificate. The sample message handlers embed these elements in the message.

The example performs the following operations:

1. Create a security token service client object (`STSService_Service`). This object manages the vCenter Single Sign On header handlers and it provides access to the vCenter Single Sign On client API methods. This example uses the issue method.
2. Create a vCenter Single Sign On header handler resolver object (`HeaderHandlerResolver`). This object acts as a container for the different handlers.
3. Add the handlers for timestamp, user credentials, certificate, and token extraction to the handler resolver.
4. Add the handler resolver to the security token service.
5. Retrieve the STS port (`STS_Service`) from the security token service object.
6. Create a security token request.
7. Set the request fields.
8. Set the endpoint in the request context. The endpoint identifies the vCenter Single Sign On Server.
9. Call the issue method, passing the token request.
10. Handle the response from the vCenter Single Sign On server.
Using Handler Methods for SOAP Headers

The VMware vCenter Single Sign On SDK provides sample code that is an extension of the JAX-WS XML Web services message handler (javax.xml.ws.handler). The sample code consists of a set of SOAP header methods and a header resolver, to which you add the handler methods. The handler methods insert timestamp, user credential, and message signature data into the SOAP security header for the request. A handler method extracts the SAML token from the vCenter Single Sign On Server response.

The VMware vCenter Single Sign On client SOAP header handler files are located in the soaphandlers directory:

SDK/sso/java/JAXWS/samples/com/vmware/sso/client/soaphandlers

To access the SOAP handler implementation, the example code contains the following import statements:

```java
import com.vmware.sso.client.soaphandlers.HeaderHandlerResolver;
import com.vmware.sso.client.soaphandlers.SSOHeaderHandler;
import com.vmware.sso.client.soaphandlers.SamlTokenExtractionHandler
import com.vmware.sso.client.soaphandlers.TimeStampHandler;
import com.vmware.sso.client.soaphandlers.UserCredentialHandler;
import com.vmware.sso.client.soaphandlers.WsSecurityUserCertificateSignatureHandler;
```

This example uses the following handler elements:

- HeaderHandlerResolver
- SamlTokenExtractionHandler
- TimestampHandler
- UserCredentialHandler
- WsSecurityUserCertificateSignatureHandler (SSOHeaderHandler)

The following sequence shows the operations and corresponding Java elements for message security.

1. Create an STS service object (STSService_Service). This object will bind the handlers to the request and provide access to the issue method.

2. Create a handler resolver object (HeaderHandlerResolver). This object acts as a receptacle for the handlers.

3. Add the header handlers:
   - Timestamp – The handler will use system time to set the timestamp values.
   - User credential – The handler requires a username and a password; it will create a username token for the supplied values.
   - User certificate signature – The handler requires a private key and an x509 certificate. The handler will use the private key to sign the body of the SOAP message (the token request), and it will embed the certificate in the SOAP security header.
   - SAML token extraction – The handler extracts the SAML token directly from vCenter Single Sign On Server response to avoid token modification by the JAX-WS bindings.

4. Add the handler resolver to the STS service.
The following code fragment creates a handler resolver and adds the handler methods to the handler resolver. After the handlers have been established, the client creates a token request and calls the Issue method. See “Sending a Request for a Security Token” on page 24.

**IMPORTANT** You must perform these steps for message security before retrieving the STS service port. An example of retrieving the STS service port is shown in “Sending a Request for a Security Token” on page 24.

**Example 3-1. Acquiring a vCenter Single Sign On Token – Soap Handlers**

```java
/*
 * Instantiate the STS Service
 */
STSService_Service stsService = new STSService_Service();

/*
 * Instantiate the HeaderHandlerResolver.
 */
HeaderHandlerResolver headerResolver = new HeaderHandlerResolver();

/*
 * Add handlers to insert a timestamp and username token into the SOAP security header
 * and sign the message.
 *
 * -- Timestamp contains the creation and expiration time for the request
 * -- UsernameToken contains the username/password
 * -- Sign the SOAP message using the combination of private key and user certificate.
 *
 * Add the TimeStampHandler
 */
headerResolver.addHandler(new TimeStampHandler());

/*
 * Add the UserCredentialHandler. arg[1] is the username; arg[2] is the password.
 */
UserCredentialHandler ucHandler = new UserCredentialHandler(args[1],args[2]);
headerResolver.addHandler(ucHandler);

/*
 * Add the message signature handler (WsSecurityUserCertificateSignatureHandler);
 * The client is responsible for supplying the private key and certificate.
 */
SSOHeaderHandler ssoHandler =
    new WsSecurityUserCertificateSignatureHandler(privateKey, userCert);
headerResolver.addHandler(ssoHandler);

/*
 * Add the token extraction handler (SamlTokenExtractionHandler).
 */
SamlTokenExtractionHandler sbHandler = new SamlTokenExtractionHandler;
headerResolver.addHandler(sbHandler);

/*
 * Set the handlerResolver for the STSService to the HeaderHandlerResolver created above.
 */
stsService.setHandlerResolver(headerResolver);
```
Sending a Request for a Security Token

After setting up the SOAP header handlers, the example creates a token request and calls the issue method. The following sequence shows the operations and corresponding Java elements.

5 Retrieve the STS service port (STSService). The service port provides access to the vCenter Single Sign On client API methods. The vCenter Single Sign On handler resolver must be associated with the STS service before you retrieve the service port. See “Using Handler Methods for SOAP Headers” on page 22.

6 Create a token request (RequestSecurityTokenType). Your vCenter Single Sign On client will pass the token request to the Issue method. The Issue method will send the token request in the body of the SOAP message. This example sets the token request fields as appropriate for a holder-of-key token request.

7 Set the token request fields.
   - lifetime – Creation and expiration times.
   - token type – urn:oasis:names:tc:SAML:2.0:assertion
   - request type – http://docs.oasis-open.org/ws-sx/ws-trust/200512/Issue
   - key type – http://docs.oasis-open.org/ws-sx/ws-trust/200512/PublicKey (for holder-of-key token type)
   - signature algorithm – http://www.w3.org/2001/04/xmlsig-more#rsa-sha256
   - renewable status

8 Set the endpoint address for the token request.

9 Call the Issue method.

10 Handle the response from the vCenter Single Sign On Server.

The following example shows Java code that performs these operations.

Example 3-2. Acquiring a vCenter Single Sign On Token – Sending the Request

```java
/*
 * Retrieve the STSServicePort from the STSService_Service object.
 */
STSService stsPort = stsService.getSTSServicePort();

/*
 * Create a token request object.
 */
RequestSecurityTokenType tokenType = new RequestSecurityTokenType();

/*
 * Create a LifetimeType object.
 */
LifetimeType lifetime = new LifetimeType();

/*
 * Derive the token creation date and time.
 * Use a GregorianCalendar to establish the current time,
```
* then use a DatatypeFactory to map the time data to XML.

```java
DatatypeFactory dtFactory = DatatypeFactory.newInstance();
GregorianCalendar cal = new GregorianCalendar(TimeZone.getTimeZone("GMT"));
XMLGregorianCalendar xmlCalendar = dtFactory.newXMLGregorianCalendar(cal);
AttributedDateTime created = new AttributedDateTime();
created.setValue(xmlCalendar.toXMLFormat());
```

/*
* Specify a time interval for token expiration (specified in milliseconds).
*/
```java
AttributedDateTime expires = new AttributedDateTime();
xmlCalendar.add(dtFactory.newDuration(30 * 60 * 1000));
expires.setValue(xmlCalendar.toXMLFormat());
```

/*
* Set the created and expires fields in the lifetime object.
*/
```java
lifetime.setCreated(created);
lifetime.setExpires(expires);
```

/*
* Set the token request fields.
*/
```java
tokenType.setTokenType("urn:oasis:names:tc:SAML:2.0:assertion");
tokenType.setRequestType("http://docs.oasis-open.org/ws-sx/ws-trust/200512/Issue");
tokenType.setLifetime(lifetime);
tokenType.setKeyType("http://docs.oasis-open.org/ws-sx/ws-trust/200512/PublicKey");
tokenType.setSignatureAlgorithm("http://www.w3.org/2001/04/xmldsig-more#rsa-sha256");
```

/*
* Specify a token that can be renewed.
*/
```
RenewingType renewing = new RenewingType();
renewing.setAllow(Boolean.TRUE);
renewing.setOK(Boolean.FALSE); // WS-Trust Profile: MUST be set to false
```

/* Get the request context and set the endpoint address. */
Map<String, Object> reqContext = ((BindingProvider) stsPort).getRequestContext();
reqContext.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, args[0]);

/*
* Use the STS port to invoke the "issue" method to acquire the token
* from the vCenter Single Sign On Server.
*/
```
RequestSecurityTokenResponseCollectionType issueResponse = stsPort.issue(tokenType);
```

/*
* Handle the response - extract the SAML token from the response. The response type
* contains the token type (SAML token type urn:oasis:names:tc:SAML:2.0:assertion).
*/
```java
RequestSecurityTokenResponseType rstResponse = issueResponse.getRequestSecurityTokenResponse();
RequestedSecurityTokenType requestedSecurityToken = rstResponse.getRequestedSecurityToken();
```

/*
* Extract the SAML token from the RequestedSecurityTokenType object.
* The generic token type (Element) corresponds to the type required
* for the SAML token handler that supports the call to LoginByToken.
*/
```
Element token = requestedSecurityToken.getAny();
This chapter describes a Java example of using the LoginByToken method.

- “vCenter Server Single Sign On Session” on page 27
- “Saving the vCenter Server Session Cookie” on page 29
- “Using LoginByToken” on page 30
- “Restoring the vCenter Server Session Cookie” on page 31

**vCenter Server Single Sign On Session**

After you obtain a SAML token from the vCenter Single Sign On Server, you can use the vSphere API method LoginByToken to establish a single sign on session with a vCenter Server. See “vCenter Single Sign On Client Example (JAX-WS)” on page 21 for an example of obtaining a vCenter Single Sign On token.

At the beginning of a vCenter Single Sign On session, your client is responsible for the following tasks:

- Maintain the vCenter session cookie. The vSphere architecture uses an HTTP cookie to support a persistent connection between a vSphere client and a vCenter Server. During the initial connection, the Server produces a session cookie. Operations during the login sequence will reset the request context so your client must save this cookie and re-introduce it at the appropriate times.

- Insert the vCenter Single Sign On token and a timestamp into the SOAP header of the LoginByToken message.

The example program uses these general steps:

1. Call the RetrieveServiceContent method to establish an HTTP connection with the vCenter Server and save the HTTP session cookie. The client uses an HTTP header handler method to extract the cookie from the vCenter Server response.

2. Call the LoginByToken method to authenticate the vCenter session. To send the token to the vCenter Server, the client uses a handler to embed the token and a time stamp in the SOAP header for the message. To identify the session started with the RetrieveServiceContent method, the client uses a handler to embed the session cookie in the HTTP header.

3. Restore the session cookie.

**HTTP and SOAP Header Handlers**

To use a vCenter Single Sign On token to login to a vCenter Server, the example uses header handlers to manipulate the HTTP and SOAP header elements of the login request. After establishing a handler, subsequent requests automatically invoke the handler.

- An extraction handler obtains the HTTP session cookie provided by the vCenter Server. After setting up the handler, a call to the RetrieveServiceContent method will invoke the handler to extract the cookie from the Server response.
Insertion handlers put the vCenter Single Sign On token and a timestamp into the SOAP header and the session cookie into the HTTP header of the login request.

The following figure shows the use of handlers to manipulate header elements when establishing a vCenter Single Sign On session with a vCenter Server.

**Figure 4-1. Starting a vCenter Session**

---

**IMPORTANT** Every call to the vCenter Server will invoke any message handlers that have been established. The overhead involved in using the SOAP and HTTP message handlers is not necessary after the session has been established. The example saves the default message handler before setting up the SOAP and HTTP handlers. After establishing the session, the example will reset the handler chain and restore the default handler.

The example code also uses multiple calls to the `VimPortType.getVimPort` method to manage the request context. The `getVimPort` method clears the HTTP request context. After each call to the `getVimPort` method, the client resets the request context endpoint address to the vCenter Server URL. After the client has obtained the session cookie, it will restore the cookie in subsequent requests.

**Sample Code**

The code examples in the following sections show how to use the `LoginByToken` method with a holder-of-key security token. The code examples are based on the sample code contained in the vCenter Single Sign On SDK. The files are located in the Java samples directory (SDK/ssoclient/java/JAXWS/samples):

- **LoginByToken sample:**
  
  `samples/com/vmware/vsphere/samples/LoginByTokenSample.java`

- **Header cookie handlers:**
  
  `samples/com/vmware/vsphere/soaphandlers/HeaderCookieHandler.java`
  `samples/com/vmware/vsphere/soaphandlers/HeaderCookieExtractionHandler.java`

- **SOAP header handlers.** These are the same handlers that are used in “vCenter Single Sign On Client Example (JAX-WS)” on page 21. The SOAP handler files are located in the vCenter Single Sign On client `soaphandlers` directory:
  
  `samples/com/vmware/sso/client/soaphandlers`
**Saving the vCenter Server Session Cookie**

The code fragment in this section establishes an HTTP session with the vCenter Server and saves the HTTP session cookie.

The following sequence describes these steps and shows the corresponding objects and methods.

1. Use the `getHandlerResolver` method to save the default message handler. To use the HTTP and SOAP message handlers, you must first save the default message handler so that you can restore it after login. The HTTP and SOAP message handlers impose overhead that is unnecessary after login.

2. Set the cookie handler. The `HeaderCookieExtractionHandler` method retrieves the HTTP cookie.

3. Get the VIM port. The VIM port provides access to the vSphere API methods, including the `LoginByToken` method.

4. Set the request context endpoint address to the vCenter Server URL.

5. Retrieve the ServiceContent. This method establishes the HTTP connection and sets the session cookie.

6. Extract the cookie and save it for later use.

The following example shows Java code that saves the session cookie.

**Example 4-1. Saving the vCenter Server Session Cookie**

```java
/*
 * The example uses a SAML token (obtained from a vCenter Single Sign On Server)
 * and the vCenter Server URL.
 * The following declarations indicate the datatypes; the token datatype (Element) corresponds
 * to the token datatype returned by the vCenter Single Sign On Server.
 * 
 * Element token; -- from vCenter Single Sign On Server
 * String vcServerUrl; -- identifies vCenter Server
 * 
 * First, save the default message handler.
 */
HandlerResolver defaultHandler = vimService.getHandlerResolver();

/*
 * Create a VIM service object.
 */
vimService = new VimService();

/*
 * Construct a managed object reference for the ServiceInstance.
 */
```
/*
ManagedObjectReference SVC_INST_REF = new ManagedObjectReference();
SVC_INST_REF.setType("ServiceInstance");
SVC_INST_REF.setValue("ServiceInstance");
/*
* Create a handler resolver.
* Create a cookie extraction handler and add it to the handler resolver.
* Set the VIM service handler resolver.
*/
HeaderCookieExtractionHandler cookieExtractor = new HeaderCookieExtractionHandler();
HeaderHandlerResolver handlerResolver = new HeaderHandlerResolver();
handlerResolver.addHandler(cookieExtractor);
vimService.setHandlerResolver(handlerResolver);

/*
* Get the VIM port for access to vSphere API methods. This call clears the request context.
*/
vimPort = vimService.getVimPort();

/*
* Get the request context and set the connection endpoint.
*/
Map<String, Object> ctxt = ((BindingProvider) vimPort).getRequestContext();
ctxt.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, vcServerUrl);
ctxt.put(BindingProvider.SESSION_MAINTAIN_PROPERTY, true);

/*
* Retrieve the ServiceContent. This call establishes the HTTP connection.
*/
serviceContent = vimPort.retrieveServiceContent(SVC_INST_REF);

/*
* Save the HTTP cookie.
*/
String cookie = cookieExtractor.getCookie();

Using LoginByToken

The code fragment in this section sets up the message handlers and calls the LoginByToken method. The following sequence describes the steps and shows the corresponding objects and methods.

1  Create a new HeaderHandlerResolver. Then set the message security handlers for cookie insertion and for inserting the SAML token and credentials in the SOAP header.

2  Get the VIM port.

3  Set the connection endpoint in the HTTP request context.

4  Call the LoginByToken method. The method invocation executes the handlers to insert the elements into the message headers. The method authenticates the session referenced by the session cookie.
The following examples shows Java code that calls the LoginByToken method.

**Example 4-2. Using LoginByToken**

```java
/*
 * Create a handler resolver and add the handlers.
 */
HeaderHandlerResolver handlerResolver = new HeaderHandlerResolver();
handlerResolver.addHandler(new TimeStampHandler());
handlerResolver.addHandler(new SamlTokenHandler(token));
handlerResolver.addHandler(new HeaderCookieHandler(cookie));
handlerResolver.addHandler(new WsSecuritySignatureAssertionHandler(
    userCert.getPrivateKey(),
    userCert.getUserCert(),
    Utils.getNodeProperty(token, "ID")));
vimService.setHandlerResolver(handlerResolver);

/*
 * Get the Vim port; this call clears the request context.
 */
vimPort = vimService.getVimPort();

/*
 * Retrieve the request context and set the server URL.
 */
Map<String, Object> ctxt = ((BindingProvider) vimPort).getRequestContext();
ctxt.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, vcServerUrl);
ctxt.put(BindingProvider.SESSION_MAINTAIN_PROPERTY, true);

/*
 * Call LoginByToken.
 */
UserSession us = vimPort.loginByToken(serviceContent.getSessionManager(), null);
```

**Restoring the vCenter Server Session Cookie**

After you log in, you must restore the standard vCenter session context. The code fragment in this section restores the default message handler and the session cookie. As the cookie handler has been replaced by the default handler, the client resets the session cookie by calling request context methods to access the context fields directly. The following sequence describes these steps and shows the corresponding objects and methods.

1. **Restore the default message handler.** The handlers used for LoginByToken are not used in subsequent calls to the vSphere API.

2. **Get the VIM port.**

3. **Set the connection endpoint in the HTTP request context.**

4. **Set the HTTP request header (vCenter session cookie).**

The following example shows Java code that restores the vCenter session. This code requires the vCenter URL and the cookie and default handler that were retrieved before login. See “Sample Code” on page 28.
Example 4-3. Restoring the vCenter Server Session

```java
/*
* Reset the default handler. This overwrites the existing handlers, effectively removing them.
*/
vimService.setHandlerResolver(defaultHandler);
vimPort = vimService.getVimPort();

/*
* Restore the connection endpoint in the request context.
*/
// Set the validated session cookie and set it in the header for once,
// JAXWS will maintain that cookie for all the subsequent requests
Map<String, Object> ctxt = ((BindingProvider) vimPort).getRequestContext();
ctxt.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, vcServerUrl);
ctxt.put(BindingProvider.SESSION_MAINTAIN_PROPERTY, true);

/*
* Reset the cookie in the request context.
*/
Map<String, List<String>> headers = (Map<String, List<String>>)
    ctxt.get(MessageContext.HTTP_REQUEST_HEADERS);
if (headers == null) {
    headers = new HashMap<String, List<String>>();
}
headers.put("Cookie", Arrays.asList(cookie));
ctxt.put(MessageContext.HTTP_REQUEST_HEADERS, headers);
```
